# CSE508 Network Security

11/9/2017 Intrusion Detection

Michalis Polychronakis

Stony Brook University

#### **Intrusion**

"Any set of actions that attempt to compromise the integrity, confidentiality or availability of information resources" [Heady et al.]

"An attack that exploits a vulnerability which results to a compromise of the security policy of the system" [Lindqvist and Jonsson]

#### Most intrusions...

Are carried out remotely

Exploit software vulnerabilities

Result in arbitrary code execution or unauthorized data access on the compromised host

Not the only way!

#### **Intrusion Method**

```
Social engineering (phishing, spam, scareware, phone call, ...)
Viruses/malware (disks, CD-ROMs, USB sticks, downloads, ...)
Network traffic interception (access credentials, keys, tokens, ...)
Password guessing (root:12345678, brute force cracking, ...)
Physical access (reboot, keylogger, screwdriver, ...)
Software vulnerability exploitation
```

#### **Attack Source**

#### Local

Unprivileged access → privilege escalation

Physical access > USB and other I/O ports, BIOS, wiretapping, memory/storage acquisition, bugging input devices, physical damage, ...

#### Remote

Internet

Local network (Ethernet, WiFi, 3/4/5G, bluetooth, ...)

Infected media (disks, CD-ROMs, USB sticks, ...)

Phone (social engineering)

Less risk, more targets...

#### **Attack Outcome**

Arbitrary code execution

Privilege escalation

Disclosure of confidential information

**Unauthorized access** 

DoS

**Erroneous output** 

Destruction

• • •

#### **Intrusion Detection**

Intrusion detection systems monitor networks or hosts for malicious activities or policy violations

**Detection (IDS):** just generate alerts and log any identified events

**Prevention (IPS):** in addition, react by blocking the detected activity

Xes 1111001 1111001 0001010

## **Defense in Depth**

#### An IDS is not a silver bullet solution

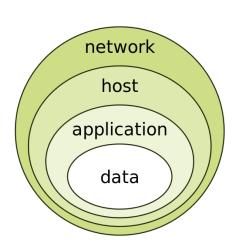

Just an additional layer of defense

Complements existing protections, detectors, and policy enforcement mechanisms

# There will always be new vulnerabilities, new exploitation techniques, and new adversaries

Single defenses may fail

Multiple and diverse defenses make the attacker's job harder

## **Defense in Depth**

## Securing systems retroactively is not always easy

WiFi access points, routers, printers, IP phones, mobile phones, legacy devices, TVs, IoT, ...

# Detecting and blocking an attack might be easier/faster than understanding and fixing the bug

Immediate response vs. long-term treatment

Patches for 0-day exploits take time to develop and deploy

## Focus not only on detecting attacks

But also on their side effects, and unexpected events in general

Example: extrusion detection/data leak prevention → detect data exfiltration

#### **Situational Awareness**

Understanding of what is happening on the network and in the IT environment

Confirm security goals Identify and respond to unanticipated events

#### Diverse sources of data

Passive/active network/host monitoring, scanning/probing, performance metrics/statistics, server/transaction logs, external (non IT) indicators, ...

Use data analytics to make sense of the increasing amount of data: identify features, derive models, observe patterns, ...

Data mining, machine learning, ...

### **Basic Concepts: Location**

### An IDS can be a separate device or a software application

Operates on captured audit data

Off-line (e.g., periodic) vs. real-time processing

#### Network (NIDS)

NetFlow records, raw packets, reassembled streams, ...

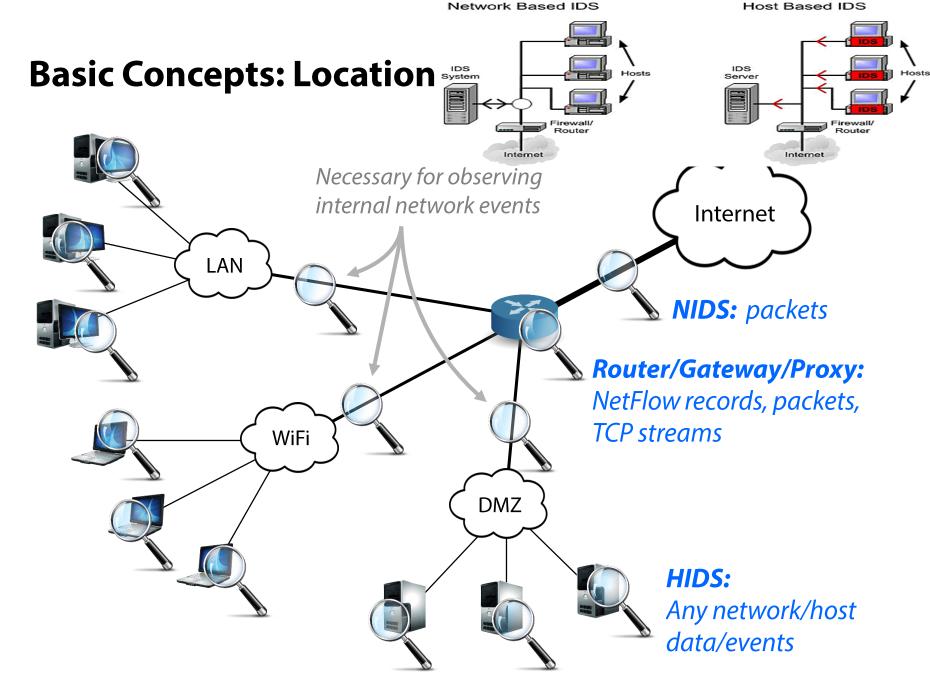

Passive (IDS) vs. in-line (IPS) operation

Examples: Snort, Bro, Suricata, many commercial boxes, ...

## Host (HIDS)

Login times, resource usage, user actions/commands, process/file/socket activity, application/system log files, registry changes, API calls, system calls, executed instructions, ...

Examples: OSquery, OSSEC, SysDig, El Jefe, AVs, registry/process/etc. monitors, network content scanners, ...

## **Deployment**

NIDS: protect many hosts with a single detector

HIDS: install detector on each host (might not always be feasible)

#### **Visibility**

NIDS: can observe broader events and global patterns

HIDS: observes only local events that might not be visible at the network

#### **Context**

*NIDS:* packets, unencrypted streams (unless proxy-level SSL inspection)

HIDS: full picture

#### **Overhead**

NIDS: none (passive)

NIPS/Proxy: adds some latency

HIDS: eats up CPU/memory (varies from negligible to complete hogging)

#### **Subversion**

NIDS: invisible in the network

NIPS/Proxy: failure may lead to unreachable network

HIDS: attacker may disable it and alter the logs (user vs. kernel level,

in-VM vs. out-of-VM, remote audit logs)

## **Basic Concepts: Detection Method**

#### Misuse detection

- Predefined patterns (known as "signatures" or "rules") of known attacks
- <sup>2</sup>Rule set must be kept up to date
- Manual vs. automated signature specification (latter is hard)
- 4 Can detect only *known* attacks, with adequate precision

## Anomaly detection

- Rely on models of "normal" behavior
- Requires (re)training with an adequate amount of data
- Can detect previously unknown attacks
- Prone to false positives

## **IDS Challenges**

## Conflicting goals

Zero false positives

#### Resilience to evasion

Detection of targeted and stealthy attacks

# Adaptability to a constantly evolving environment

New threats, new topology, new services, new users, ...

Rule sets must be kept up to date according to new threats

Models must be updated/retrained (concept drift)

## Coping with an increasing amount of data

# **Popular Open-source Signature-based NIDS**

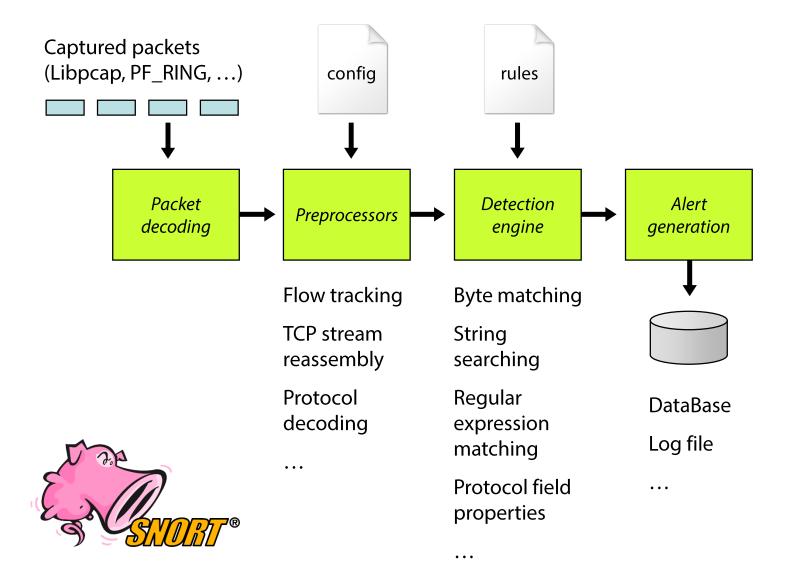

Snort Bro Suricata

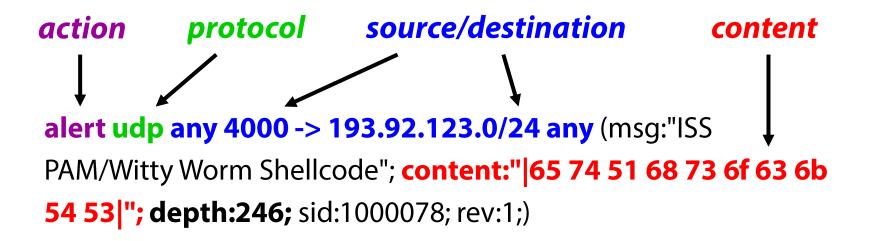

#### **Use Case: Snort**

## What is a Signature?

An attack description as seen at Layer 2-7

Example Snort signature for Witty worm:

```
◐
                               Shell - Konsole <2>
                                                                          _ _ ×

```

## **More Examples**

## String searching

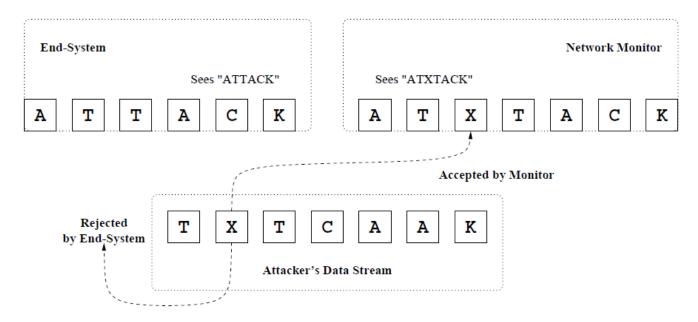

```
alert ip $EXTERNAL_NET $SHELLCODE_PORTS -> $HOME_NET any
(msg:"SHELLCODE Linux shellcode"; content:"|90 90 90 E8 C0 FF
FF FF|/bin/sh"; classtype:shellcode-detect; sid:652; rev:9;)
```

## Strsearch + regexp matching + stateful inspection

## **Stateful Inspection**

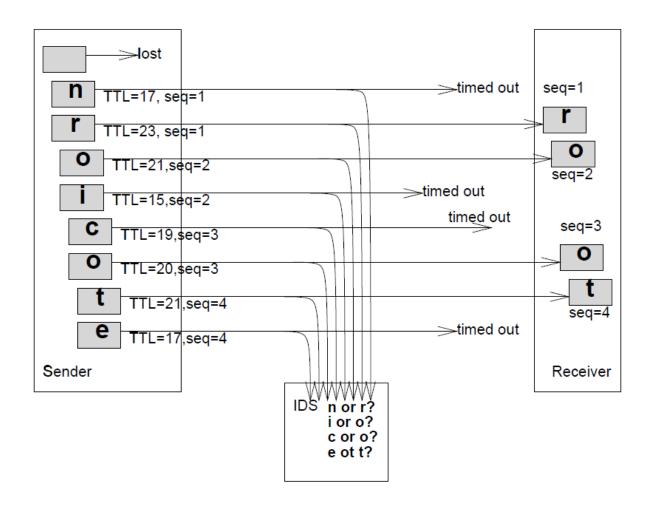

Semantic gap: NIDS processes individual packets, while applications see a contiguous stream (TCP)

#### Potential for evasion

Solution: IP defragmentation, TCP stream reassembly Flow-level tracking: group packets into flows, track TCP state Stream reassembly: normalize and merge packets into streams

### Different TCP stacks may treat corner cases differently...

## **Anomaly Detection**

Training phase: build models of normal behavior

Detection phase: alert on deviations from the model

## Many approaches

Statistical methods, rule-based expert systems, clustering, state series modeling, artificial neural networks, support vector machines, outlier detection schemes, ...

## Good for noisy attacks

Port scanning, failed login attempts, DoS, worms, ...

#### Good for "stable" environments

E.g., web server vs. user workstation

## **Anomaly Detection**

## Learning

Supervised: Labels available for both benign data and attacks Semi-supervised: Labels available only for benign data Unsupervised: No labels: assume that anomalies are very rare compared to benign events

## Many possible features

Packet fields, payload content, connection properties, traffic flows, network metrics, system call sequences, code fragments, file attributes, statistics, ...

## **Evaluating Intrusion Detection Systems**

Accuracy is not a sufficient metric!

Example: data set with 99.9% benign and 0.1% malicious events

Dummy detector that marks everything as benign has 99.9% accuracy...

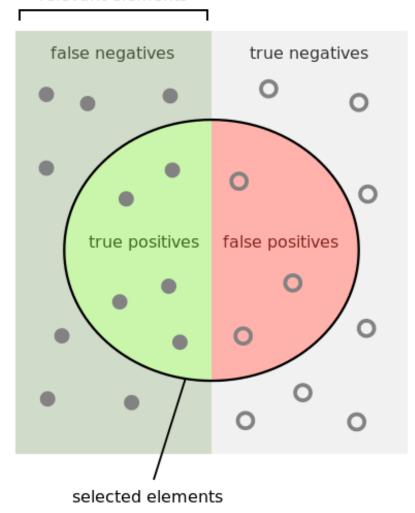

False positive: legitimate behavior was deemed malicious

False negative: an actual attack was not detected

#### **Detection Result**

		Positive (alert)	Negative (silence)
Event	Positive (malicious)	TP	FN
Actual	Negative (benign)	FP	TN

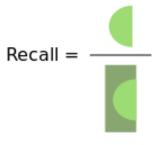

#### relevant elements

How many selected items are relevant?

How many relevant items are selected?

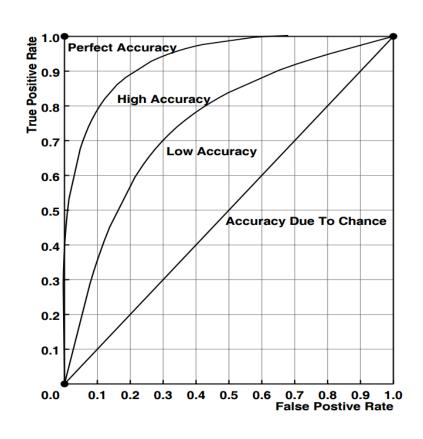

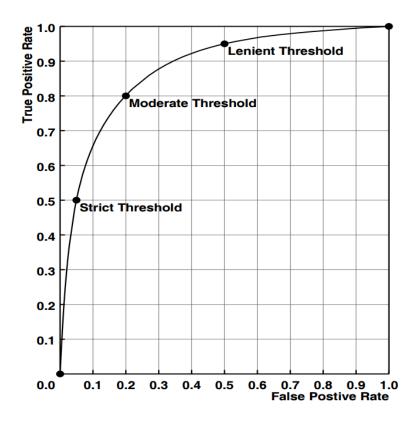

## **Receiver Operating Characteristic (ROC) Curve**

### Concise representation of a detector's accuracy

Y axis: success rate of detecting signal events

X axis: error rate of falsely identifying noise events

## **Evasion** – "Stay under the radar"

# Both anomaly and misuse detection systems can be evaded by breaking the detector's assumptions

Detectors rely on certain features

Make those features look legitimate or at least non-suspicious

## Many techniques

Fragmentation

Content mutation/polymorphism/metamorphism

Mimicry

Rate adjustment (slow and stealthy vs. fast and noisy)

Distribution and coordination (e.g., DoS vs. DDoS)

Spoofing and stepping stones

. . .
